Experiment No. 05

Code:

```
.model small
.stack 100h

.data
    num1 dw 0011h  ; First 16-bit number
    num2 dw 0011h  ; Second 16-bit number
    result dw 0    ; To store the result

.code
main:
    ; Initialize data segment
    mov ax, @data
    mov ds, ax

    ; Load num1 into AX
    mov ax, num1

    ; Add num2 to AX
    add ax, num2
    ; Store the result in 'result'
    mov result, ax
    ; Exit the program
    mov ah, 4Ch
    int 21h

end main
```

CONCLUSION:

In these assembly language programs, we successfully implemented algorithms to determine the largest and smallest numbers from a given series of hexadecimal values stored in the data segment.

Finding the Largest Number:

The program initializes a data series and compares each element sequentially. It stores the largest value found and displays it as output.

Finding the Smallest Number:

A similar approach is used to determine the smallest number. The program iterates through the data series, updating the smallest value found.

Conclusion:

In this experiment, we successfully implemented a recursive procedure to compute the factorial of a positive integer using assembly language.

1. Recursive Function Implementation:

The factorial function (fact) calls itself until n = 1, at which point it returns 1. The result of n * (n-1)! Is computed using stack operations (push and pop).

2. Stack Utilization:

The program utilizes the stack to store intermediate values, ensuring that the function operates correctly through recursive calls.

3. Factorial Computation:

The final result is stored in the DX register, showcasing correct multiplication and recursive execution.

This experiment demonstrates the application of recursion in assembly language and provides insight into how function calls works.
